Exercise 3.1

Do you know these wooden Russian dolls, where smaller ones are contained in bigger ones? Here is schematic picture of such dolls.

First, write a knowledge base using the predicate directlyIn/2 which encodes which doll is directly contained in which other doll. Then, define a (recursive) predicate in/2, that tells us which doll is (directly or indirectly) contained in which other doll. E.g. the query in (katarina, natasha) should evaluate to true, while in (olga, katarina) should fail.

```
directlyIn(katarina,olga).
directlyIn(olga,natsha).
directlyIn(natsha,irina).
in(X,Y) :- directlyIn(X,Y).
in(X,Y) :- directlyIn(X,Z), in(Z,Y).
```

Exercise 3.2

Define a predicate $greater_than/2$ that takes two numerals in the notation that we introduced in this lecture (i.e. 0, succ(0), succ(succ(0)) ...) as arguments and decides whether the first one is greater than the second one. E.g:

```
?- greater_than(succ(succ(0))), succ(0)).
yes
?- greater_than(succ(succ(0)), succ(succ(succ(0)))).
```

```
greater_than(succ(X),0).
greater_than(succ(X),succ(Y)) :- greater_than(X,Y).
```

Exercise 3.3

Binary trees are trees where all internal nodes have exactly two childresn. The smallest binary trees consist of only one leaf node. We will represent leaf nodes as leaf(Label). For instance, leaf(3) and leaf(7) are leaf nodes, and therefore small binary trees. Given two binary trees B1 and B2 we can combine them into one binary tree using the predicate tree: tree(B1, B2). So, from the leaves leaf(1) and leaf(2) we can build the binary tree tree(leaf(1), leaf(2)). And from the binary trees tree(leaf(1), leaf(2)), leaf(4)).

Now, define a predicate swap/2, which produces a mirror image of the binary tree that is its first argument. For example:

```
?- swap(tree(tree(leaf(1), leaf(2)), leaf(4)),T).

T = tree(leaf(4), tree(leaf(2), leaf(1))).

yes
swap(leaf(X),leaf(X)).
swap(tree(X1,Y1),tree(Y2,X2)) :- swap(X1,X2), swap(Y1,Y2).
```

Exercise 3.4

In the lecture, we saw the predicate

```
\label{eq:descend} \begin{array}{ll} \operatorname{descend}\left(X,Y\right) & :- \operatorname{child}\left(X,Y\right). \\ \\ \operatorname{descend}\left(X,Y\right) & :- \operatorname{child}\left(X,Z\right), \\ \\ \operatorname{descend}\left(Z,Y\right). \end{array}
```

Could we have formulated this predicate as follows?

```
\begin{aligned} \operatorname{descend}\left(X,Y\right) &:= \operatorname{child}\left(X,Y\right). \\ \operatorname{descend}\left(X,Y\right) &:= \operatorname{descend}\left(X,Z\right), \\ \operatorname{descend}\left(Z,Y\right). \end{aligned}
```

Compare the declarative and the procedural meaning of this predicate definition.

Hint: What happens when you ask the query descend (rose, martha)?

```
The declarative meaning of both predicate definitions is the same; the procedural meaning of both is different. The latter can result in an "Out of local stack" exception as Prolog recursively attempts to unify Z.
```

Exercise 3.5

We have the following knowledge base:

```
directTrain(forbach, saarbruecken).
directTrain(freyming, forbach).
directTrain(fahlquemont, stAvold).
directTrain(stAvold, forbach).
directTrain(saarbruecken, dudweiler).
directTrain(metz, fahlquemont).
directTrain(nancy, metz).
```

That is, this knowledge base holds facts about towns it is possible to travel between by taking a direct train. But of course, we can travel further by 'chaining together' direct train journeys. Write a recursive predicate travelBetween/2 that tells us when we can travel by train between two towns. For example, when given the query

```
\label{eq:travelBetween (nancy, saarbruecken).} it \ should \ reply \ `yes'. \ travelBetween (X,Y) := directTrain (X,Y). \ travelBetween (X,Y) := directTrain (X,Z), \ travelBetween (Z,Y).
```

It is, furthermore, plausible to assume that whenever it is possible to take a direct train from A to B, it is also possible to take a direct train from B to A. Can you encode this in Prolog? You program should e.g. answer 'yes' to the following query:

```
\label{eq:travelBetween} travelBetween (saarbruecken, nancy) . \label{eq:travelBetween} travelBetween (X,Y) := directTrain(X,Y) . \label{eq:travelBetween} travelBetween(X,Y) := directTrain(Y,X) .
```

```
\texttt{travelBetween}\,(\mathtt{X},\mathtt{Y}) \; :- \; \texttt{directTrain}\,(\mathtt{Y},\mathtt{Z})\,, \; \; \texttt{travelBetween}\,(\mathtt{Z},\mathtt{X})\,.
```

Do you see any problems your program may run into?

Some paths may result in an infinite loop.
